

# Estimating phylogenetic trees with phangorn (Version 0.99-3)

Klaus P. Schliep\*

October 30, 2009

## 1 Introduction

These notes should enable the user to estimate phylogenetic trees from alignment data with different methods using the *phangorn* package. For more background on all the methods see e.g. [2, 7]. This document illustrates some of the *phangorn* features to estimate phylogenetic trees using different reconstruction methods. Small adaptations to the scripts in 6 should enable the user to perform phylogenetic analysis.

## 2 Getting started

The first thing we have to do is to read in an alignment. Unfortunately there exists many different file formats alignments can be stored in. The function `read.phyDat` is used to read in an alignment. There are several functions to read in alignments depending on the format of the dataset (nexus, phylip, fasta) and the kind of data (amino acid or nucleotides) in the *ape* package [3] and *phangorn*. The function `read.phyDat` calls these other functions. For the specific parameter settings available look in the help files of the function `read.dna` (for phylip, fasta, clustal format), `read.nexus.data` for nexus files. For amino acid data additional `read.aa` is called. We start our analysis the *phangorn* package and then load in an alignment.

```
> library(phangorn)
> primates = read.phyDat("primates.dna", format = "phylip",
+   type = "DNA")
```

---

### 3 Distance based methods

After reading in the alignment we can build a first tree with distance based methods. The function `dist.dna` from the `ape` package computes distances for many DNA substitution models. To use the function `dist.dna` we have to transform the data to class `DNABin`. For amino acids the function `dist.ml` offers common substitution models ("WAG", "Dayhoff", "JTT" and "LG"). After constructing a distance matrix we reconstruct a rooted tree with UPGMA and alternatively an unrooted tree using Neighbor Joining [5, 6].

```
> dm = dist.dna(as.DNABin(primates))
> treeUPGMA = upgma(dm)
> treeNJ = NJ(dm)
```

We can use the plot the trees `treeUPGMA` and `treeNJ` (figure 1) with the commands:

```
> par(mfrow = c(1, 2), mar = c(1, 1, 4, 1))
> plot(treeUPGMA, main = "UPGMA")
> plot(treeNJ, "unrooted", main = "NJ")
```

Distance based methods are very fast and we will use the UPGMA and NJ tree as starting trees for the maximum parsimony and maximum likelihood analysis.

### 4 Parsimony

The function `parsimony` returns the parsimony score, that is the number of changes which are at least necessary to describe the data for a given tree. We can compare the parsimony score of the two trees we computed so far:

```
> parsimony(treeUPGMA, primates)
[1] 751
> parsimony(treeNJ, primates)
[1] 746
```

We can use the function `optim.parsimony` performs tree rearrangements to find trees with a lower parsimony score. So far the only tree rearrangement implemented is nearest-neighbor interchanges (NNI).

```
> treePars = optim.parsimony(treeUPGMA, primates)
optimize topology: 751 --> 746
optimize topology: 746 --> 746
Final p-score 746 after 1 nni operations
> parsimony(treePars, primates)
[1] 746
```

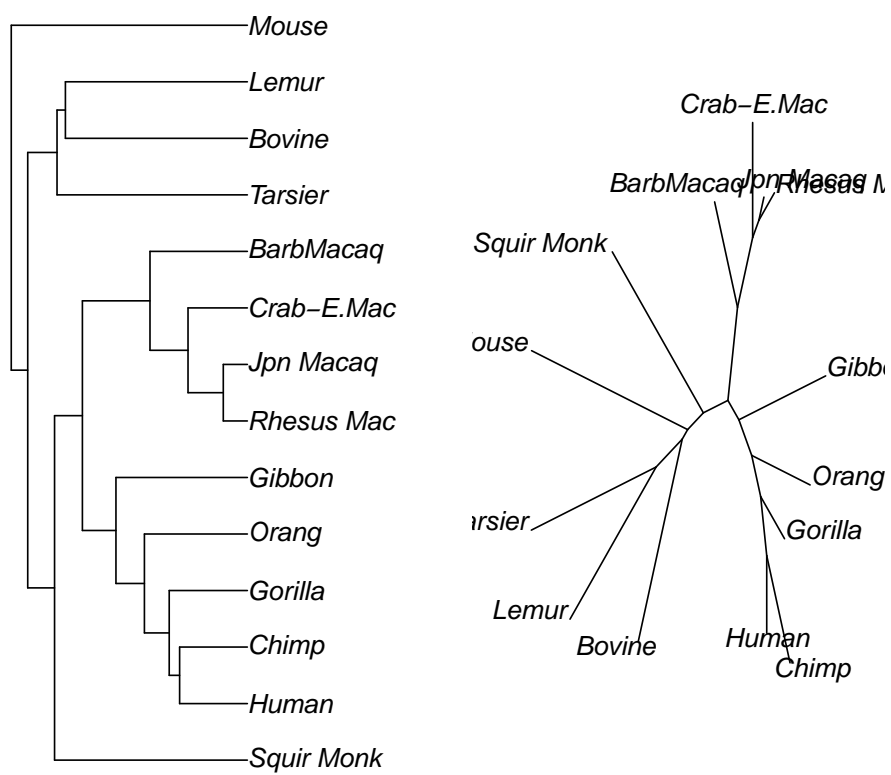

Figure 1: Rooted UPGMA tree and unrooted NJ tree

## 5 Maximum likelihood

The last method we will describe in this vignette is Maximum Likelihood (ML) as introduced by Felsenstein [1]. We can easily compute the likelihood for a tree given the data

```
> fit = pml(treeNJ, data = primates)
> fit
loglikelihood: -3077.846

unconstrained loglikelihood: -1230.335

Rate matrix:
  a c g t
a 0 1 1 1
c 1 0 1 1
g 1 1 0 1
t 1 1 1 0

Base frequencies:
0.25 0.25 0.25 0.25
```

The function `pml` returns an object of class `pml`. This object contains the data, the tree and many different parameters of the model like the likelihood etc. There are many generic functions for the class `pml` available.

The object `fit` just estimated the likelihood for the tree it got supplied, but the branch length are not optimized for for the Jukes-Cantor model yet, which can be done with the function `optim.pml`.

```
> fitJC = optim.pml(fit, TRUE)
> logLik(fitJC)
```

With the default values `pml` will estimate a Jukes-Cantor model. The function `update.pml` allows to change parameters. We will change the model to the GTR +  $\Gamma(4)$  + I model and then optimize all the parameters.

```
> fitGTR = update(fit, k = 4, inv = 0.2)
> fitGTR = optim.pml(fitGTR, TRUE, TRUE, TRUE, TRUE, TRUE)

> fitGTR
loglikelihood: -2609.589

unconstrained loglikelihood: -1230.335
```

```

Proportion of invariant sites: 0.006045091
Discrete gamma model
Number of rate categories: 4
Shape parameter: 3.175621

```

```
Rate matrix:
```

```

      a      c      g      t
a 0.0000000 0.6234388 32.36012 0.3867576
c 0.6234388 0.0000000 0.00000 13.8337583
g 32.3601231 0.0000000 0.00000 1.0000000
t 0.3867576 13.8337583 1.00000 0.0000000

```

```
Base frequencies:
```

```
0.3918068 0.3795443 0.04024686 0.1884020
```

We can compare the trees for the JC and GTR +  $\Gamma(4)$  + I model with the AIC

```

> AIC(fitGTR)
[1] 5293.178
> AIC(fitJC)
[1] 6186.59

```

or the Shimodaira-Hasegawa test.

```

> SH.test(fitGTR, fitJC)
      Trees      ln L Diff ln L p-value
[1,]      1 -2609.589    0.0000 0.5012
[2,]      2 -3068.295  458.7061 0.0000

```

## 6 Appendix: Standard scripts for nucleotide or amino acid analysis

Here we provide two standard scripts which can be adapted for the most common tasks. Most likely the arguments for `read.phyDat` have to be adapted to accommodate your file format. The bootstrap analysis can be computational demanding.

```

> file = "myfile"
> dat = read.phyDat(file)
> dm = dist.ml(dat)
> tree = NJ(dm)
> fitNJ = pml(tree, dat, k = 4, inv = 0.2)
> fit = optim.pml(fitNJ, TRUE, TRUE, TRUE, TRUE, TRUE)
> fit

```

You can specify different several models build in which you can specify "WAG", "JTT", "Dayhoff", "LG". Optimising the rate matrix for amino acids is possible, but would take a long, a very long time. So make sure to set `optBf=FALSE` and `optQ=FALSE` in the function `optim.pml`, which is also the default.

```
> file = "myfile"
> dat = read.phyDat(file, type = "AA")
> dm = dist.ml(dat, model = "JTT")
> tree = NJ(dm)
> fitNJ = pml(tree, dat, model = "JTT", k = 4, inv = 0.2)
> fit = optim.pml(fitNJ, optNni = TRUE, optInv = TRUE,
+   optGamma = TRUE)
> fit
```
